How are blood cells normally produced? 2, 3

Blood cells develop through a process called haematopoiesis. This involves bone marrow and part of the lymphatic system.

Bone marrow contains unspecialised cells known as haematopoietic stem cells. As they divide and mature, they become more specialised and develop into one of the three types of blood cell, each with a specific function.

Blood cells only last for a limited period of time, and so they constantly need to be replaced in the correct numbers to meet the body’s needs. One of the key functions of the spleen is to remove worn out blood cells from circulation. An additional component of blood is plasma.

What causes blood cancer? 1

To function properly, the body needs to produce exactly the right amount of each type of blood cell. Blood cancers develop when damage occurs to vital genes, disrupting the normal lifecycle of blood cells, and upsetting this balance. Risk factors include:

- Infection
- Low immunity
- Radiation
- Chemotherapy
- Genetic disorders
- Chemical exposure
- Environmental factors
- Autoimmune disorders

What are the symptoms of blood cancer? 4

Many symptoms of blood cancer are a result of fewer healthy, functioning blood cells, or overproduction of abnormal cells, causing a lack of space where blood cells are produced, i.e. bone marrow and the lymphatic system.

Symptoms of blood cancer can vary, but commonly include:

- **Tiredness**
- **Breathlessness**
  - Caused by a decrease in red blood cells

- **Swollen/painful glands**
- **Bone pain**
  - Caused by a build-up of abnormal blood cells in bone marrow and lymphatic system

- **Bruising**
- **Bleeding**
  - Caused by a decrease in platelets

- **Infections**
- **Fever**
  - Caused by a decrease in white blood cells

- **Unexplained or unexpected weight loss**
How are blood cancers classified? 1, 5–12

There are 140 different types of blood cancer, which can be classified in three main groups

### Leukaemia
A cancer of white blood cells
Classified by:
- Type of white blood cell affected
- Whether the disease is acute (progressing quickly) or chronic (progressing slowly)

≈1 in 3 cancers in children in industrialised countries is a leukaemia
≈40% of leukaemias are classified as chronic lymphocytic leukaemia

### Lymphoma
A cancer that starts in the lymphatic system
Two main types:
- Hodgkin lymphoma (HL)
- Non-Hodgkin lymphoma (NHL)

Lymphoma is the most common blood cancer

### Myeloma
A cancer of plasma cells in the bone marrow
The cancerous plasma cells also produce large amounts of an abnormal antibody (also known as an immunoglobulin), causing impairment of organs or tissue.

≈40,000 people develop myeloma in Europe each year

For more information on disease burden and prevalence please visit www.diseaselens.com

Other blood disorders closely related to blood cancers and that may develop into leukaemia, include:

#### Myelodysplastic syndrome
Some blood cells made in the bone marrow are damaged resulting in a lack of healthy blood cells being released into the bloodstream

#### Myeloproliferative neoplasm
Too many of one or more types of blood cell are made in the bone marrow
